[^] A: The raw content is already in the ascii-encoded stream, but only the content you are interested in is present and decoded. The square brackets [^] are the regex pattern of the particular format of the tags. The backslash is escape sequence (to match the same as seen in the source) instead of the literal character. If you open the file with e.g. an editor, you will see that the raw content is not put into the stream: UnicodeDecodeError: 'utf8' codec can't decode bytes in position 22-23: invalid start byte This is because the decoder expects a ByteSequence, not a stream of bytes. So, you can use the stream directly, but Python's built-in stdlib modules might not be capable of decoding such a stream. You can read the content manually by writing code that splits the content by the regular expression pattern, or by using a "decoder" module that is able to decode a stream of bytes. For example, here is a code that decodes the content from the string you provided, and prints it: 

```
import re # let the editor open the input file for us # (for example, using the 'vi' command) with open('/tmp/sample.dat', 'r') as fin: # assuming the input file begins with the first "[^]" # we can read the first 22 characters from the stream # and discard them new_content = fin.read(22) # and
```

---

print it (note that stdlib modules are not able # to decode the content, so we need to do it manually) for line in new\_content.split(b' '):  
print(re.findall(b'^\[[.+?]+\\$', line)) For a more robust and Pythonic approach, you should consider the third-party library that is capable of decoding the tags format of the given file. For example, the csv module is able to decode the format and to read and/or write the content into a CSV file. from csv import DictWriter, UnicodeEncodeError import re # open the CSV file using the c

A: From the few lines in your post there's a few options for you. You can read this file as an XML file and then load it ( I have never used this but seems simple and easy ) Or if you can read a CSV file, ( from your question it looks like that is the case) then you can use R's read.csv() And if there are a bunch of lines in the file one after the other that fit your requirements, you can read each line of the file, chunked like so: `chunks = unlist(strsplit(str, "\\r\\n", fixed = FALSE))` Then you can either use `sapply()` or `foreach()` to loop through each chunk of each line. I'm not sure how you'd parse the lines if you have any newline characters in them ( but seems unlikely ) so I've written in the first case.

Q: File search using `execl()` is creating a new process I am using `execl("/usr/bin/find", "find", "-name", "metadata-list.xml", NULL)` to execute a shell script and then load the specified xml file and parse it. The find command is working without errors. I am unable to figure out why the process is getting created, with the new process getting created as well. The process that is getting created is something like this: `sununiformity tty0 SUS 0:15 e79caf774b`
